SUSTAINABILITY, DURABILITY, AND EASE OF USE

DRIVE EXTERIOR WOOD COATING DEVELOPMENTS

Despite growing interest around the world in the use of concrete and composite materials, wood remains widely used in exterior architectural applications, including siding, decking, fencing, and similar applications. Coatings continue to play an important role in maintaining the appearance and protecting the integrity of wood. Exterior wood has conveyed quality and beauty for centuries, but that beauty requires significant maintenance.

Architectural wood coatings continue to reduce that maintenance cycle while further enhancing its allure, thus supporting a healthy market," asserts Jon Felders, Dow Coating Materials, North America business director. There are differences in the use of wood on a regional basis and, therefore, different requirements and preferences for types of wood coatings. Developments in technology, however, are largely driven by three key goals: to improve sustainability; to enhance durability and extend painting cycles, and to reduce the time and effort required to complete coating projects.

Regional differences in the use of exterior wood are caused mainly by differences in preferred building materials and varying economic growth rates, according to Erik Pras, global marketing director for Versatic® Acid & Derivatives at Hexion. For example, he notes that in North America and Northern Europe, the use of wood as an exterior building material is popular, while in Central Europe and high-growth parts of Asia, concrete is mainly used. Similarly, wood is not a common substrate in architectural exterior applications in South America. The use of wood decking is growing in China, however, according to Melanie Bauer, global marketing director for Coatings with Mefilon. "Affluent Asian buyers are purchasing larger homes with decks made out of wood and pavers," she says. "She adds that in southern and Central Europe, homeowners who would typically use pine are switching to more tropical hardwoods that do not need as much protection, but are coated to improve their visual appearance. Also in Europe and the United States, there is a move away from traditional wood decking and siding towards stamped concrete and wood composites, according to Bauer. Increasing popularity of the "weathered" look is also reducing the use of coatings for protection, but creating greater demand for stains that produce this appearance while still protecting the wood.

Despite these various shifts in the market, wood remains the primary choice for commercial and residential applications due to its wide availability, according to Ravvichandran, vice president of R&D at Xing Industries. "While composite decking materials have been available in the marketplace for a while and even though many manufacturers have greatly improved the look and feel of these types of materials (i.e., more like natural wood), natural wood is still largely the substrate of choice for consumers looking for exterior wood surfaces," agrees Nick Ruizta, director of product marketing at The Behr Paint Company. And strong housing markets continue to drive demand for wood coatings. In the United States, according to Ravvichandran, baby boomers are downsizing to updated smaller homes. There is also a trend to extend interior stain colors to exterior spaces such as decks and patios to facilitate more connectedness to nature and seamless interior/exterior transitions that allow extension of the indoor living space to the outdoors. Felders adds that in North America, in particular, many people are in fact expanding their interior living spaces by adding decks. "Decks not only allow people to enjoy the outdoors, they often provide a return on investment comparable to updating a kitchen," Felders observes.

WOOD COATING DEVELOPMENTS

Despite growing interest around the world in the use of concrete and composite materials, wood remains widely used in exterior architectural applications, including siding, decking, fencing, and similar applications. Coatings continue to play an important role in maintaining the appearance and protecting the integrity of wood. "Exterior wood is conveyed quality and beauty for centuries, but that beauty requires significant maintenance. Architectural wood coatings continue to reduce that maintenance cycle while further enhancing its allure, thus supporting a healthy market," asserts Jon Fedders, Dow Coating Materials, North America business director. There are differences in the use of wood on a regional basis and, therefore, different requirements and preferences for types of wood coatings. Developments in technology, however, are largely driven by three key goals: to improve sustainability; to enhance durability and extend painting cycles; and to reduce the time and effort required to complete coating projects.

Regional differences in the use of exterior wood are caused mainly by differences in preferred building materials and varying economic growth rates, according to Erik Pras, global marketing director for Versatic® Acids & Derivatives at Hexion. For example, he notes that in North America and Northern Europe, the use of wood as an exterior building material is popular, while in Central Europe and high-growth parts of Asia, concrete is mainly used. Similarly, wood is not a common substrate in architectural exterior applications in South America. The use of wood decking is growing in China, however, according to Melanie Bauer, global marketing director for Coatings with Mebicma. "Affluent Asian buyers are purchasing larger homes with decks made out of wood and pavers," she says. She adds that in Southern and Central Europe, homeowners who would typically use pine are switching to more tropical hardwoods that do not need as much protection, but are coated to improve their visual appearance. Also, in Europe and the United States, there is a move away from traditional wood decking and siding towards stamped concrete and wood composites, according to Bauer. Increasing popularity of the "weathered" look is also reducing the use of coatings for protection, but creating greater demand for stains that produce this appearance while still protecting the wood.

Despite these various shifts in the market, wood remains the primary choice for commercial and residential applications due to its wide availability, according to Ravishankar, vice president of R&D, Kanga Industries. "While composite decking materials have been available in the marketplace for a while and even though many manufacturers have greatly improved the look and feel of these types of materials (i.e., more like natural wood), natural wood is still largely the substrate of choice for consumers looking for exterior wood surfaces," agrees Chuck Miatina, director of product marketing at The Behr Paint Company. And strong housing markets continue to drive demand for wood coatings. In the United States, according to Ravishankar, baby boomers are downsizing to updated smaller homes. There is also a trend to extend interior stain colors to exterior spaces such as decks and patios to facilitate more connectedness to nature and a seamless transition that allows extension of the indoor living space to the outdoors. Fedders adds that in North America, in particular, many people are in fact expanding their interior living spaces by adding decks. "Decks not only allow people to enjoy the outdoors, they often provide a return on investment comparable to updating a kitchen," Fedders observes.
OPTIMIZED PERFORMANCE: THE SHIFT FROM DIY TO DIFM

Overall, the global market for wood coatings in exterior architectural application is a healthy business with strong growth opportunities, asserts Gerjan van Laar, market segment manager for Designer Coatings at TNK Benecol Resins. Rising disposable income is increasing the demand for premium wood coatings. “People are willing to pay more for unique appearances and functional products that help them fulfill their needs. There is, for instance, a huge movement towards water-based coatings, because consumers actually admire the natural beauty of surfaces like concrete and wood.”

There is a huge movement towards water-based coatings, because consumers really admire the natural beauty of surfaces like concrete and wood.”

According to van Laar, AkoNovel has observed that the increasing cost and lack of availability of contractors labor is driving a shift from in-field finished to in-factory finished products, according to Anthony Woods, segment market manager for Wood Coatings in the company’s Industrial Coatings business. “The quality and durability of in-factory finishes are allowing the transition from factory-printed to fully factory-finished products,” he asserts. The increasing use of other substrates and the factory-applied coating of certain construction components are additional factors contributing to greater opportunities in the renovation and maintenance areas, adds van Laar. “Efficiency and ease of use are increasingly driving product development in the industry, as the shortage of professional painters around the world is pushing the demand for their time and costs solutions.” He adds, with respect to cost, Pias notes that water-based coatings are an important factor, but in some regions, labor is much more important. In these cases, increased coating lifetimes for reduced recoating frequency are of great interest. “End users and contractors want more ‘bang for their buck’,” he says. “Cost performance continues to be an important balance,” he notes. Simplifying stain projects and solving wood-related problems continue to drive innovation in this category, according to Bautista, with quicker return to service an important factor for both DIY and professional customers alike. Optimized performance for the construction industry and DIY consumers is driving the market, agrees Bauer. She identifies flame retardant coatings and coatings that offer ease of application (fewer coats needed for protection and visual appeal) as two examples. There is also a push for multipurpose products that can be used in interior and exterior applications and on both wood and metal, coatings that perform well on both wood and wood-plastic composite materials. Seeborne coatings are able to perform well to that of solvent-based systems, and solbarene coatings that provide better penetration into softwoods and cedar at similar or lower solvent levels, according to Pias. Due to climate change, van Laar observes that the weather has become very unpredictable, and coatings for exterior surfaces have more to endure, increasing the importance of performance indicators such as dirt pick-up, drying time, weather resistance, and durability/longevity.

MEETING THE DEMAND FOR SUSTAINABLE PRODUCTS

Increasing the sustainability of exterior architectural wood coatings is also essential today. Regulations and labeling requirements are both being fine-tuned, and toxic ingredients are being banned from paint formulations, according to van Laar. The specifics of regulations, much like preferences, tend to be regional. The Bio-Based Product Regulation (BBPR) in the region has also made it increasingly difficult to register primers and impregnants to protect exterior wood, observes Wood. The demand for waterborne wood coatings is also on the rise in China due to the new tax implemented by the government to reduce pollution, according to Bautista. There is also interest in high-solids solbarene coatings around the world. In the United States, Bauer points out that approximately 40% of exterior wood coatings supplied today are solbarene based because professional contractors prefer the performance of solbarene-based products. “High-solids producers would prefer the switch to waterborne systems for low VOC, that will only happen when waterborne systems perform the same as, or better than solbarene-based products,” she states. Despite this performance issue, van Laar notes that painters and applicators are more proactive with awareness of their safety and health, and companies are making different choices and choosing paints that prevent health issues for their employees. “The sustainability of products and application techniques is still a high priority, and consumer awareness is driving improvements in their production,” Woods adds. Building managers and homeowners are taking sustainability into account in their purchasing decisions, notes Bautista, who know how to reduce the carbon footprint of their building assets at a maintenance or renovation level. Van Laar adds. “The sustainability value of coating technology is fast becoming a key product differentiator, with more painters focusing on the environmental and health safety impact of their consumer choices and professional activities,” he concludes.

SELECTION OF OPTIMAL PRODUCTS

The choice of wood coating is based on several factors, including the type of wood, its condition, the application, preference for solvent or water-based systems, and, of course, cost. Typically, clear or semi-transparent coatings are used to help keep the natural wood color and highlight the unique characteristics of the wood. The color coatings are applied to slightly aged or stained wood, and thicker, heavier coatings are used to cover wood that has been neglected but is still structurally sound, adds Fidessi. With respect to resin choice, the most common technologies used in the exterior wood coating market are alkyls, acrylics, and urethanes, and selection depends on the specific performance requirements. “Each of these technologies has specific benefits for end uses, and it is very different per region which technology is preferred by the painters or end users,” van Laar comments. The top waterborne systems include acrylics, alkyls, and acrylic hybrids, while alkyls are the main resin type used in solbarene-based systems, according to Bauer. Going forward, van Laar expects that hybrid and triblock solutions will be needed to meet evolving design and market needs. Solbarene-based alkyls are fast-drying, cost-effective, and can provide a matte to glossy appearance. “Alkyl is still the leading chemistry because it works, is economic, and these applications are well-tested and accepted,” asserts Prus. He also notes that contractors want systems that perform as tried and true with no headache after application (i.e., claims, return visits, defects), while the DIY market wants easy to apply and clean systems. Alkyl can meet all of these requirements. For decks and fencing in Europe and the United States, high penetrating coatings rather than film formers are generally used, according to Bauer. Options include linseed oil, tung oil, oil, and wood oils because they allow for a more natural appearance of the wood. She adds that professionals in the U.S. market also prefer oil-based products because they offer re-coating opportunities and a sustainable revenue stream without film forming or sheen. For siding, however, while a small segment of consumers desires traditional oil-based stains, water-based, acrylic systems.

Approximately 40% of exterior wood coatings used today are solarene-based. Approximately 40% of exterior wood coatings used today are solarene-based.

The switch from solbarene to waterborne systems is one of the key drivers of new technology development. “As more countries implement stricter regulations and ecolabelling requirements, formulators are challenged to develop waterborne systems that maintain the same functionality as traditional solbarene coatings,” says Fidessi. In addition, the Do It Yourself (DIY) market, according to van Laar, is “at the forefront of a trend toward shift toward solid color stains, as opposed to less opaque stains, due to their durability and longer warranties. Moving from Solvent-Borne to Water-Borne

The switch from solbarene to waterborne systems is one of the key drivers of new technology development. Loved producer facility in Bumba, Sweden.
OPTIMIZED PERFORMANCE: THE SHIFT FROM DIY TO DIFM

Overall, the global market for wood coatings in exterior architectural application is a healthy business with strong growth opportunities, asserts Gerjan van Laar, market segment manager for Decorative Coatings at DSM Decorative Resins. Rising disposable income is increasing the demand for premium wood coatings. “People are willing to pay more for unique appearances and functional products that help them fulfill their needs. There is, for instance, a huge movement towards natural coatings, because consumers really admire the natural beauty of surfaces like concrete and wood,” he comments. “In addition, due to the movement from Do It Yourself (DIY) to Do It For Me (DIFM) in both Europe and North America, we have seen an increasing demand for renovation in the professional paint market,” he remarks. Contractor labor shortages are complicating this situation. “People are spending their times differently because consumer behavior is changing. For example, millennials and generation Xers are outsourcing the practical jobs more than the baby boom generation did. At the same time, there is a shortage of professional painters in mature economies, which is leading to increasing demand and a relatively small workforce,” says van Laar. AkzoNobel has observed that the increasing cost and lack of availability of contractor labor is driving a shift from in-field finished to in-factory finished products, according to Anthony Woods, segment marketing director for Wood Coatings in the company’s Industrial Coatings business. “The quality and durability of in-factory finishes are allowing the transition from factory-painted to fully factory-finished products,” he asserts. The increasing use of other substrates and the factory-applied coating of certain construction components are additional factors contributing to greater opportunities in the renovation and maintenance market areas, adds van Laar. “Efficiency and ease of use are increasingly driving product development in the industry, as the shortage of professional paint workers around the world is pushing the demand for those types of coating solutions,” he adds. With respect to cost, Praz notes that cost is an important but in some regions, labor is much more important. In these cases, increased coating lifetimes for reduced recoating frequency are of great interest. “End users and contractors want more bang for their buck,” says Praz. “So cost-performance continues to be an important balance,” he notes. Simplifying stain projects and solving wood-related problems continue to drive innovations in this category, according to Bautista, with quicker return to service an important focus for both DIY and professional customers alike. Optimized performance for the construction industry and DIY consumers is driving the market, agrees Bauer. She identifies flame retardant coatings and coatings that offer ease of application (fewer coats needed for protection and visual appeal) as two examples. There is also a push for multipurpose products that can be used in interior and exterior applications and on both wood and metal, coatings that perform well on both wood and wood-plastic composite materials. “The covalent covalent coating forperformance equal to that of solvent-based systems, and solvent-free coatings that provide better penetration into softwoods and cedar at similar or lower solvent levels, according to Praz. Due to climate change, van Laar observes that the weather has become very unpredictable, and coatings on exterior surfaces have more to endure, increasing the importance of performance indicators such as dirt pick-up, drying time, weather resistance, and durability/longevity.

MEETING THE DEMAND FOR SUSTAINABLE PRODUCTS

Increasing the sustainability of exterior architectural wood coatings is also essential today. Regulations and labeling requirements are both being fine-tuned, and toxic ingredients are being banned from paint formulations, according to van Laar. The specifics of regulations, much like preferences, tend to be regional. The Ecolabel requirements in Europe are driving products to more waterborne systems, according to Bauer. The Biocidal product regulation (BPR) in the region has also made it increasingly difficult to register products and impregnants to protect exterior wood, observes Wood. “The demand for waterborne exterior wood coatings is also on the rise in China due to the new tax implemented by the government to reduce pollution, which benefits from wood products. There is also interest in high-quality solvent-borne coatings around the world. In the United States, NAF Bauer points out that approximately 40% of exterior wood coatings used today are solvent-based because professional contractors prefer the performance of solvent-based products. “Although producers would prefer the switch to waterborne systems for low VOC, that will only happen when waterborne products perform as well as, or better than, solvent-based products,” she states. Despite this performance issue, van Laar notes that painters and applicators are more proactive about their safety and health, and companies are making different choices and choosing paints that prevent health issues for their employees. “The sustainability of products and application techniques is still a high priority, and consumers want to see improvements in their purchase and life cycle,” she says. Another factor that know how to reduce the carbon footprint of their building assets at a maintenance or renovation level, van Laar adds. “The sustainability value of coating technology is fast becoming a key product differentiator, with more painters focusing on the environmental and health impact of their consumer choices and professional activities,” he concludes.

SELECTION OF OPTIMAL PRODUCTS

The choice of wood coating is based on several factors, including the type of wood, its condition, the application, preference for solvent or water-based systems, and, of course, cost. Typically, clear or semi-transparent coatings are used on deck boards, but the top color coatings are applied to slightly aged or stained wood, and richer textures are achieved with exterior wood coatings that are wood-based. The demand for waterborne exterior wood coatings is also on the rise in China due to the new tax implemented by the government to reduce pollution, which benefits from wood products. There is also interest in high-quality solvent-borne coatings around the world. In the United States, NAF Bauer points out that approximately 40% of exterior wood coatings used today are solvent-based because professional contractors prefer the performance of solvent-based products. “Although producers would prefer the switch to waterborne systems for low VOC, that will only happen when waterborne products perform as well as, or better than, solvent-based products,” she states. Despite this performance issue, van Laar notes that painters and applicators are more proactive about their safety and health, and companies are making different choices and choosing paints that prevent health issues for their employees. “The sustainability of products and application techniques is still a high priority, and consumers want to see improvements in their purchase and life cycle,” she says. Another factor that know how to reduce the carbon footprint of their building assets at a maintenance or renovation level, van Laar adds. “The sustainability value of coating technology is fast becoming a key product differentiator, with more painters focusing on the environmental and health impact of their consumer choices and professional activities,” he concludes.

At approximately 40% of exterior wood coatings used today are solvent-based.
EXTERIOR WOOD COATING DEVELOPMENTS

Technologies that are enabling optimization of durability and penetration capabilities include water-reducible alkyds and/or acrylic hybrids. Other technologies being investigated include sol-gel chemistry, waterborne micelles, micro-emulsion reactions, self-assembled structures, nano materials, and nano technology.

applications. Exterior architectural coatings must also be fast drying, have low odor, and offer enhanced durability and protection for extended product lifetimes, according to Pras.

Once again, different members of the value chain have different performance requirements that impact coating development. Overall, Raiser says that ease of application/formulation with improved brushability, non-drip coatings, recoatability, and longevity drive innovation, but longevity is more important in Europe where some manufacturers offer 10-year warranties, while in the United States, DIY consumers continue to look for water-reducible and non-drip coatings. Paint producers, meanwhile, want to formulate with fewer additives and are looking to resin manufacturers to help with multiple performance properties like matting, abrasion resistance, and leveling that are enabling optimization of durability and penetration capabilities include water-reducible alkyds and/or acrylic hybrids,” Raiser notes. She adds that VOC is in research underway to determine if improvement in rheology leads to improved brushability and if coatings can be developed that can be successfully applied under non-ideal conditions, such as to wet wood. Other technologies being investigated, according to Ravichandran, include sol-gel chemistry, waterborne micelles, micro-emulsion reactions, self-assembled structures, nano materials, and nano technology, with a focus on the synergistic action of these technologies for the development of coatings that afford scratch resistant, antibacterial, dust-repellent, and/or self-healing surfaces.

IMPROVING EFFICIENCY

Margin compression across the value chain has led to a widespread introduction of cost and production efficiency measures to add value to the total cost of ownership and formulation, van Laar says. Higher levels of mechanical and chemical resistance have been achieved in recent years, extending the maintenance intervals for exterior architectural wood coatings. Use of additives like colloidal silica has made it possible to achieve the same results in waterborne coatings, such as dic pick-up resistance and excellent durability, that have been achieved only with solventborne coating formulations, facilitating the move to more sustainable solutions, according to McRilland. The incorporation of higher levels of bio-based content into coating solutions, without sacrificing functional performance, has also enabled lower carbon footprints and stronger environmental profiles, according to van Laar. As an example, he points to DSM’s Discovery® SP-2022 XP Resin, a self-mattir bio-based solution for protecting the natural beauty of surfaces. “Coatings formulated with this resin offer outstanding ultra-solventless aesthetics and high performance that customers and consumers demand, while greatly improving production efficiency and ensuring respect for the health of people and the planet,” van Laar asserts.

Behr focuses on the development of products that reduce the return-to-service time and help mitigate environmental elements. One example is BEHR Premium Quick Dry Oil Base Wood Finish, which can be applied to damp wood, dries in 60 minutes (dramatically faster than other oil-based stai); resists rain after 60 minutes, and allows the user to prep, stain, and entertain all in the same day (as opposed to the two- to three-day turnaround time of a typical stain project), according to Buehner. Water-based acrylic coatings with erosion failures have been another important development, says Fedders, because they provide acrylic durability without undesirable flaking failures that require re-sanding. He also points to the development of next-generation resination coatings, now on the market, that minimize flaking failures and greatly extend the lifetime of decks. “Cool” deck coatings that do not attract heat are also adding in this market, according to Buehner.

Flexon, meanwhile, is seeing increased interest in affordable truly 1K moisture-curable systems for exterior architectural applications. In response, the company has developed Veely’s™ silane technology comprising Veely’s vinyl ester and silane monomers. “This isocyanate-free platform allows customers to tailor their products for the desired end uses, balancing hard-ness and flexibility and pot life and cure speed, while also delivering similar performance to that of 2K polyurethane coatings,” says Pras.

TECHNOLOGY TRENDS

Current research covers many different areas. Nouryon, for instance, is focused on achieving anti-soiling properties on its Levens Coloidal Silica product across different waterborne coatings applications. Hexeon continues to develop technologies that close the gap in performance between waterborne and solvent-based exterior wood coatings, including acrylic emulsions based on extremely hydrophobic monomers for improved water repellency and superior durability, waterborne dispersions that can be formulated totally solvent-free, and 5H-emulsions with improved appearance and high crosslink densities. Michelman is also working on improving the performance, ease of application, and penetration of waterborne products, as well as enhancing the long-term mildew and mold resistance of wood coatings to eliminate the need for use of cleaning solutions that damage the wood and potentially the landscaping around it. AkzoNobel expects to see a move towards UV in the future, enabling customers to benefit from production efficiencies. “100% UV coatings allow for very fast curing, with many lines running at over 100 feet/minute, and also provide excellent chemical resistance and toughness,” Woods explains. He does note, though, that the development profile of reactive UV oligomers means this technology is not generally suitable for spraying. Instead, solventborne or, more commonly, waterborne UV is used when topcoats are needed. Waterborne UV is already growing in popularity in North America due to its similar application characteristics and tougher, more durable finish.

A LOOK AT FACTORY-APPLIED EXTERIOR WOOD COATINGS

“Overall, innovations in formulated coatings for exterior architectural/wood products are being driven by the desire for higher productivity through faster application and shorter cure times, coupled with the need to resist blocking and provide good finish resistance. There is also a constant drive to improve the durability of exterior products. The design of exterior coatings has always been a balance between developing a coating flexible enough to deal with the dimensional instability of the substrate, and the durability demands of dirt pick-up resistance, toughness, and gloss retention. The recent development of 100% UV products is probably the most significant step in the industrial wood coatings. These coatings deliver improved durability combined with a step change in production costs,” Woods states. Within the waterborne field, he observes that the constant improvement of core shell and gradient latex technology is also improving durability. In particular, he points to nanocore shell latices, which give excellent wood penetration to improve aesthetics while also delivering the required performance. Woods also observes that the use of the chemically modified wood acryl acetylation volatilizing set contribution to resistance, longevity, life, and improved durability (100%) in primer, drying and cladding applications is creating opportunities for the development of new coating systems that match the advances in the material itself. Finally, AkzoNobel has also observed an increasing use of renewable materials for resin manufacturing and more non-biobased products that provide strong anti-fouling protection while avoiding the leaching of biocides from the wood substitute coating.

Use of additives like colloidal silica has made it possible to achieve the same results in waterborne coatings, such as dirt pick-up resistance and excellent durability that have been achieved only with solventborne coating formulations.
